

Nevis Canonical Data Model (simplified)

This is the target model. Your job is to land the client's source data into these five entities. It is intentionally simplified (real Nevis has more), but the grain and the constraints below are the ones that matter for this exercise.

Everything is at the level of a **household**: a household groups the people (clients), the money (accounts), the advisor who owns the relationship, and the interactions (meetings and calls) the firm has had with them.

household

field	type	notes
household_id	string (PK)	canonical id you generate; stable across syncs
household_name	string	
primary_advisor_id	string (FK → advisor)	exactly one per household, required
status	enum	ACTIVE INACTIVE PROSPECT
as_of_date	date	as-of for the household's rolled-up figures
source_tags	string[]	optional; free lineage/annotation tags

client (a person)

field	type	notes
client_id	string (PK)	
household_id	string (FK → household)	required
first_name	string	
last_name	string	

field	type	notes
role	enum	PRIMARY SPOUSE DEPENDENT SIGNER OTHER
source_tags	string[]	optional; free annotation/lineage tags (see rule 6)

account (an investment account)

field	type	notes
account_id	string (PK)	
household_id	string (FK → household)	required; every account rolls up to a household
account_type	enum	INDIVIDUAL JOINT TRUST IRA ROTH_IRA CORPORATE OTHER
market_value_usd	number, nullable	see rules
currency_original	string	source currency before conversion
as_of_date	date	
custodian	string	

advisor

field	type	notes
advisor_id	string (PK)	
full_name	string	
role	string	

interaction (a meeting or call with a household)

field	type	notes
interaction_id	string (PK)	
household_id	string (FK → household)	required; every interaction rolls up to a household
interaction_type	enum	REVIEW PROSPECTING ONBOARDING OTHER
interaction_date	date	
advisor_id	string (FK → advisor), nullable	who ran/attended it
summary	string, nullable	free-text note from the meeting page body

Canonical rules (these are what the mapping must satisfy)

1. **One primary advisor per household.** Required and non-null.
2. **AUM is market value in USD.** household AUM is the sum of its accounts' `market_value_usd`.
3. **Unknown ≠ zero.** A household with no known accounts has AUM null, not 0.
4. **Every account rolls up to exactly one household.** No orphan accounts in the final canonical output.
5. **Currency.** If a source amount is not USD, it must be converted before it lands in `market_value_usd`, and `currency_original` must record the original currency.
6. **Fields with no first-class home.** A CRM property that has no dedicated column above is your call: preserve business-meaningful ones as `source_tags` / annotations, normalize where it helps, drop what is truly irrelevant, and flag genuine contradictions. Silently dropping a meaningful attribute, and dumping everything into flags, are both wrong.
7. **Every interaction rolls up to exactly one household.** Resolve an interaction's client to an existing household, and do **not** mint a new household from an interaction. An interaction whose client cannot be matched is an orphan → flag (the mirror of rule 4).
